

Association of Denovo Copy Number Variants with Oral Clefts

Rob Scharpf

June 24, 2012

Cleft lip

Unilateral incomplete

Unilateral complete

Bilateral complete

Cleft palate, cleft lip and palate

Incomplete cleft palate

Unilateral complete lip and
palate

Bilateral complete lip and
palate

Goal

To identify structural variants contributing to oral cleft:

- denovo CNV discovery (by-sample)
- compare denovo frequency among oral cleft offspring to *similar* controls

Sample size

	Cleft	Controls
Discovery	2082	752
WGA	120	99
MAD > 0.3	212	138
non-EA	1090	-
n	660	515

- cell frequencies are the number of Father-Mother-Offspring trios
- The controls are trios with dental caries.

Illumina 610 quad: Distance between markers

Low level summaries

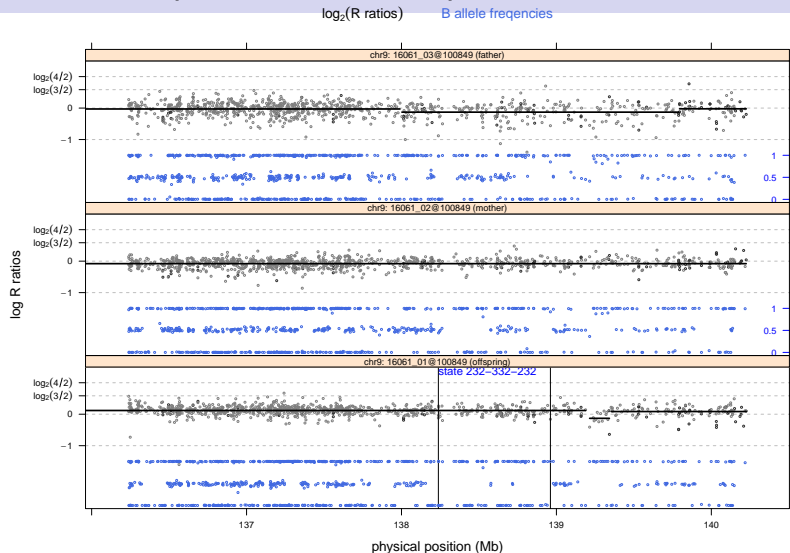

B allele frequencies

\log_2 R ratios

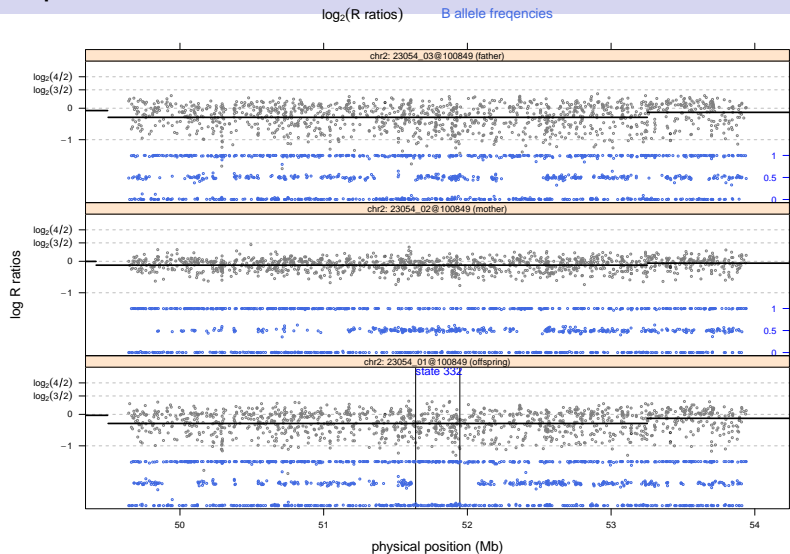

Data for case-parent trio: false positive

PennCNV joint HMM: '332' is denovo hemizygous deletion

False positives

Computational characteristics

- The joint HMM is ≈ 3 hours per trio
- $3 * 2082$ trios $\approx 6,246$ CPU hours

```
$ qstat -u hschwend
```

The minimum distance

$$\text{minimum distance} \equiv (r_O - r_F) \times I_{[|r_O - r_F| > |r_O - r_M|]} + (r_O - r_M) \times I_{[|r_O - r_F| \leq |r_O - r_M|]}$$

False positives

False positives

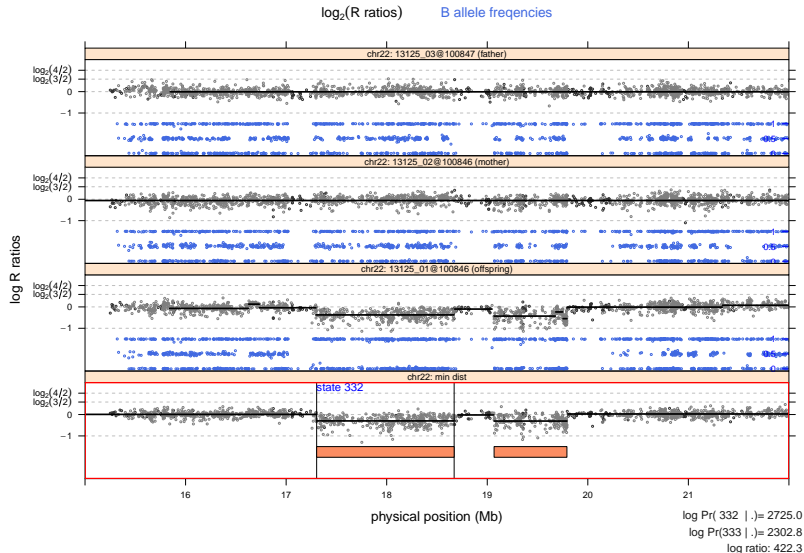

Algorithm

- 1 Calculate the minimum distance
- 2 Segment the minimum distance
- 3 Posterior classification

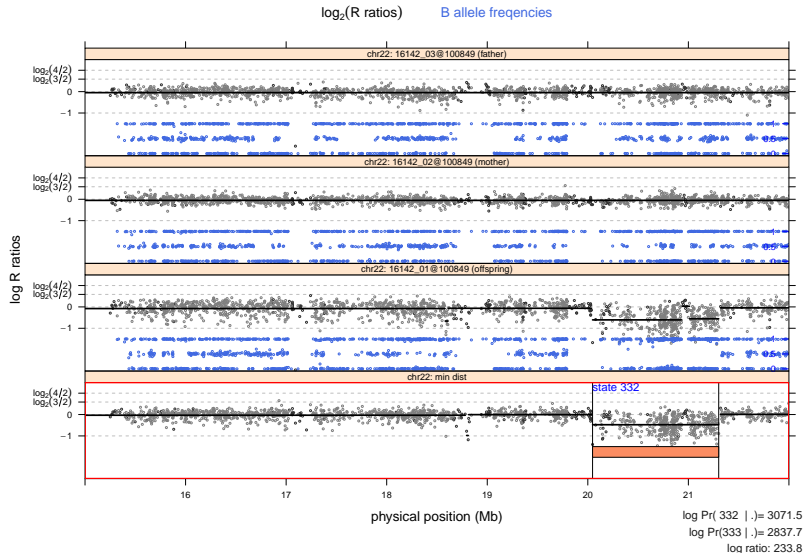

Computational characteristics

- 591 CPU hours (versus 6,246)
- When multiple CPUs are detected, the MinimumDistance R package parallelizes by chromosome
 - ▶ system time \approx 1 day

Chromosome 7

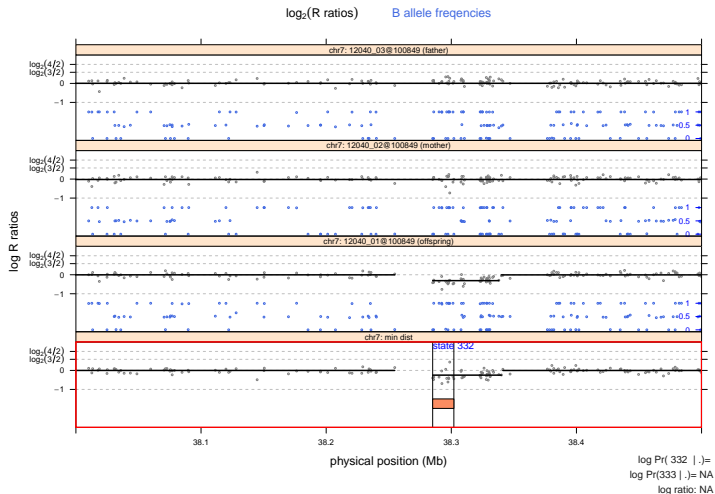

Chromosome 7

Conclusions

- False positives are problematic using standard approaches for de novo CNV discovery
- Oral cleft offspring tend to have slightly bigger denovo deletions than in the controls, and the deletions tended to be closer to coding regions of the genome
- The association of the chromosome 7 region was statistically significant after adjusting for multiple testing.
- The association study used a small fraction of the available oral cleft data.
